New Nationwide Study Indicates Patients Are Often Prescribed Potentially Futile Drugs in Their Final Months of Life

Nearly half of older adults in Sweden take ten or more medications in their last months of life, according to a new study reported in The American Journal of Medicine

Philadelphia, PA, May 15, 2017 – Older adults often receive drugs of questionable benefit during their last months of life, according to the first study conducted on the burden of end-of-life medications across an entire population. The authors advocate for clinical guidelines to support physicians when they face the decision to continue or discontinue medications near the end of life. Their findings are published in The American Journal of Medicine.

The simultaneous use of multiple medications has become commonplace among older adults. In high-income countries, it has previously been estimated that 25% to 40% of people aged 65 years or older are prescribed at least five medications. This practice is known as “polypharmacy,” and can lead to drug-drug interactions and serious adverse effects.

In the context of end-of-life care, polypharmacy also raises important ethical questions about the potential futility of treatments close to death.

“People with life-limiting illness often receive medications whose benefit is unlikely to be achieved within their remaining lifespan,” writes lead author Lucas Morin, of the Aging Research Center at Karolinska Institutet in Stockholm, Sweden. “However, previous studies have been conducted in selected samples of individuals. Future research and clinical guidelines need to be informed by findings that are generalizable beyond a specific illness or care setting.”

The authors identified over half a million adults over 65 years of age who died in Sweden between 2007 and 2013, and reconstructed their drug prescription history for each of the last 12 months of life through the Swedish Prescribed Drug Register. The characteristics of study participants at time of death were assessed through record linkage with the National Patient Register, the Social Services
Register, and the Swedish Education Register. Of note, over-the-counter drugs were not taken into account in this investigation.

The study resulted in two main findings:

First, the burden of medications increases as death approaches. The proportion of older adults exposed to at least ten different prescription drugs rose from 30% to 47% over the course of the last year before death. Older adults who died from cancer had the largest increase in the number of drugs. Individuals living in institutions were found to receive a greater number of medications than those living in the community, but the number of drugs increased more slowly for those living in an institution.

Second, the researchers found that polypharmacy near the end of life is fueled not only by drugs prescribed for the purpose of symptom management (e.g. analgesics), but also by the frequent continuation of long-term preventive treatments and disease-targeted drugs. For instance, during their last month of life, a large proportion of older adults used platelet antiaggregants (45%), beta-blockers (41%), ACE inhibitors (21%), vasodilators (17%), statins (16%), calcium channel blockers (15%), or potassium-sparing agents (12%).

“The clinical benefit of drugs aiming at preventing cardiovascular diseases during the final month of life is at the very least questionable. Physicians should consider discontinuing drugs that may be effective and otherwise appropriate, but whose potential harms outweigh the benefits that patients can reasonably expect before death occurs.” However, the authors noted that “the process of de-prescribing requires timely dialogue between the patient, family, and physician, and close monitoring of symptoms. It is also essential that patients and their relatives receive clear information about their options in terms of palliative care in order to counter the feeling of abandonment that they may experience when treatments are withdrawn.”

The authors call for the development of clinical guidelines to support physicians in their effort to reduce potentially futile drug treatments near the end of life.

About The American Journal of Medicine
The American Journal of Medicine (http://www.amjmed.com), known as the “Green Journal,” is one of the oldest and most prestigious general internal medicine journals published in the United States. It has an Impact Factor of 5.61 and is ranked #13 out of 151 General and Internal Medicine titles based on number of total citations, according to the 2015 Journal Citation Reports® published by Thomson Reuters.
AJM, the official journal of The Association of Professors of Medicine, a group comprised of chairs of departments of internal medicine at 125-plus US medical schools, publishes peer-reviewed, original scientific studies that have direct clinical significance. The information contained in this article in The American Journal of Medicine is not a substitute for medical advice or treatment, and the Journal recommends consultation with your physician or healthcare professional. AJM is published by Elsevier.

About Elsevier
Elsevier is a global information analytics company that helps institutions and professionals progress science, advance healthcare and improve performance for the benefit of humanity. Elsevier provides digital solutions and tools in the areas of strategic research management, R&D performance, clinical decision support, and professional education; including ScienceDirect, Scopus, ClinicalKey and Sherpath. Elsevier publishes over 2,500 digitized journals, including The Lancet and Cell, more than 35,000 e-book titles and many iconic reference works, including Gray’s Anatomy. Elsevier is part of RELX Group, a global provider of information and analytics for professionals and business customers across industries. www.elsevier.com
