ABSTRACT

Idiopathic pulmonary fibrosis is a progressive disease, with a high mortality within the first 3-5 years from diagnosis and a poor quality of life mainly because of the burden of symptoms, such as dyspnea and cough, occurring usually many months before the diagnosis. Although available antifibrotic therapies slow down disease progression, they have no impact on quality of life. Moreover, health care around idiopathic pulmonary fibrosis patients is often “disease-centered” and relies on clinical surrogate outcomes that are poorly related to patients’ quality of life and disease experience.

Therefore, patients with idiopathic pulmonary fibrosis have several unmet needs in all domains of health that they wish to see recognized and addressed in the context of the treatment of their disease and its complications.

In this review, we summarize the care pathway from the patients’ perspective, identifying current gaps in care, education, support, and communication among patients with IPF, their caregivers, and care teams during the patient journey. The role of patient-reported outcomes (PROs), PRO measures (PROMs), and patient-reported experience measures (PREMs) in their care is discussed, as well as the need of disease-specific PROs, PROMs, and PREMs.

INTRODUCTION

Patient experience is an important quality index of health care, and the use of patient-reported outcome (PRO), patient-reported outcome measures (PROMs), and patient-reported experience measures (PREMs) is recommended for measuring the performance of health care systems worldwide.^{1,2} In fact, there is an increasing recognition of the need to include patient perspectives among the outcomes of medical care.^{1,3} Policy makers and funding and regulatory bodies recognize that the lack of patient-centered care results in unmet patient needs, high costs, and ultimately ineffective care.^{4,5} Historically, clinicians and researchers have favored “objective” outcomes, such as mortality, for the assessment of efficacy of medical interventions. Unfortunately, these measures do not always align with what is most important to the patients

(ie, the impact of disease on their well-being and their ability to live a fulfilling life⁵), creating unmet needs, and care gaps.⁶ The development and use of PRO and related measures is an attempt to include patient perspectives in designing systems and approaches that can truly meet their needs.⁴

Idiopathic pulmonary fibrosis is a progressive disease with a high mortality in 3-5 years from diagnosis.^{7,8} It is characterized by poor quality of life and high symptom burden.^{9,10} Current idiopathic pulmonary fibrosis care delivery models do not address patient needs. As a result, patient advocacy bodies have generated calls for action to develop a holistic approach to idiopathic pulmonary fibrosis patient care,¹¹⁻¹³ with the aim to include good quality care at all stages of disease.^{10,14} A holistic approach should address disease management as well as individual patient concerns.¹⁵

The lack of appropriate and dedicated tools such as PROs and their respective measures (PROMs, PREMs) in idiopathic pulmonary fibrosis contributed to current gaps in the field.^{11,12}

In this review, we summarize the available evidence on what patients with idiopathic pulmonary fibrosis and their caregivers value and what they perceive as care gaps; finally, we highlight the urgent need to develop and validate disease-specific PROMS and PREMS.^{16,17}

PROS, PATIENT-REPORTED EXPERIENCES, AND THEIR MEASURES

PROs are directly reported by patients and provide information about the perspective on their own health status and quality of life in the context of a disease and its treatments.¹⁸ Patient-reported experiences (PREs) describe how patients experience health care and reflect patient perspectives on various facets of the care processes. They are also self-reported interpretation¹⁹ from patients and their families, representing a valuable opinion to assess quality and to improve health care.²⁰

PROMs are dedicated tools to assess health outcomes and patients' quality of life.^{21,22} They are multidimensional because they address various domains, such as symptoms, functional status, psychological, social, and spiritual well-being. Different types of PROMs are available: they can be classified as generic or disease- or domain-specific.^{18,22} Generic PROMs are useful for the whole population (healthy and diseased) and focus on function, independence, and mood. Disease-specific PROMs focus impact of a single disease or group of diseases, such as on various

aspects of patient's life. Domain-specific PROMs are focused on particular symptom (eg, dyspnea) or organ or systems (eg, gastrointestinal, colorectal).

PREMs are tools to gather data on patient views of their health care experience rather than on outcomes. They indirectly assess the quality of care, and they can be classified as relational or functional.¹⁹ Relational PREMs focus on

patients' experience of their relationship with the care team. Functional PREMs focus on objective experience of care facilities (eg, type of care model, support, waiting times, access, cleanliness, comfort). PREMs can be generic or disease specific.¹⁹

The Food and Drug Administration (FDA) and the Patient-Centered Outcome Research Institute (PCORI) have released guidelines to help researchers develop and use PROs and PROMs in research.¹⁸ They recommend that studies of any intervention should include the impact on PROs, PROMs, and PREMs.^{16,18} There is increasing recognition that clinical care also benefits from their use.²³⁻²⁵ Incorporation of PROs in clinics can facilitate a multidimensional, patient-centered evaluation of

the disease, identify unmet needs, direct clinician attention to these needs, and better inform policy makers in the light of identified patient goals.^{11,16,17} The use of PREMs can impact the quality of patient-provider communication by facilitating inclusion of patient perspectives and their narratives.²⁶⁻²⁹

CLINICAL SIGNIFICANCE

- Several unmet needs of patients, caregivers, and health care providers were identified in the idiopathic pulmonary fibrosis patient pathway, from early diagnosis to end of life.
- Disease-specific patient-reported experience measures (PREMs) and patient-reported outcomes measures (PROMs) offer the opportunity to fill the current gaps in the health care of these patients.
- A clear understanding of the patient pathway is paramount to implement patient-centered health care, research, and education in this particular patient group.

PROMS AND PREMS FOR IDIOPATHIC PULMONARY FIBROSIS

Targeted strategies to improve patient-centered care, quality of life, and patient experience are paramount in a progressive disease such as idiopathic pulmonary fibrosis.⁹ Unfortunately, all major idiopathic pulmonary fibrosis clinical trials focused on objective measures such as lung function, and PROMs have only been used as secondary endpoints.^{30,31} The past decade has seen an increase in PROMs use in idiopathic pulmonary fibrosis, generally including dyspnea and cough questionnaires, quality of life measures, and depression and anxiety questionnaires.⁹ Generic PROMs such as Euroqol-5D and short form-36 have been used in this condition.^{32,33} Disease-specific PROMs, such as Saint George Respiratory Questionnaire (SGRQ)³⁴ and COPD assessment Test (CAT),³⁵ although not specific for idiopathic pulmonary fibrosis, have also been used. In addition, idiopathic pulmonary fibrosis-specific tools such as SGRQ-IPF,³⁶ the cross Atlantic tool to assess quality of life in IPF (ATAQ-IPF-ca)^{3,7} and King's Brief Interstitial Lung Disease (K-BILD)

questionnaire³⁸ were also developed. There are several other specific questionnaires in various stages of development: “Living with IPF” (L-IPF)³⁹ was reviewed by the FDA and is undergoing further validation testing; “IPF-PROM”⁴⁰ is currently under development. The other domain-specific PROMs used in idiopathic pulmonary fibrosis are the University of California San Diego Shortness of Breath Questionnaire (UCSD SOB)⁴¹ and the modified Medical Research Council Dyspnea Questionnaire (mMRC);⁴² and again the K-BILD,³⁸ the SGRQ-IPF,³⁶ and the ATAQ-ca³⁷ for dyspnea; the Leicester Cough Questionnaire (LCQ)⁴³ and the Cough Quality of Life Questionnaire (CQLQ)⁴⁴ for cough; as well as the Hospital Anxiety and Depression Scale (HADS) for anxiety and depression.⁴⁵

Currently, there are no PREMs available for clinical use. The Patient Experiences and Satisfaction with Medications (PESaM)⁴⁶ questionnaire is an example for idiopathic pulmonary fibrosis PREM that was developed to assess patient experiences with pirfenidone for the treatment of the disease and it is awaiting a validation study.

THE PATIENT PATHWAY IN IDIOPATHIC PULMONARY FIBROSIS AND THE PATIENT-CENTERED APPROACH

The diagnosis and treatment of this disease is a complex clinical process, involving a multidisciplinary team.^{47,48} Most patients describe the diagnostic process as a major struggle because of lack of awareness, delayed access to tertiary centers, lack of patient-centered care, and lack of reliable information about the disease (Table 1).

At least 3 important overlapping phases are included in the patient pathway: 1) early and confident diagnosis; 2) progression of the disease; and 3) end of life. Needs assessment, individualized care delivery, timely communication, and planning should support the patients in all the phases of their journey with the disease.^{9,12} Appropriate and precise tools, such as PROMs and PREMs, should be used by the multidisciplinary team to understand the complexity of the patients' condition and to tailor supportive care.^{9,13}

Tables 1 and 2 report the main pitfalls of the current care of patients with idiopathic pulmonary fibrosis. They identify gaps in the current clinic models and provide suggestions for the use of PROMs.

EARLY AND ACCURATE DIAGNOSIS WITH PATIENT-CENTERED EDUCATION AND SUPPORT

Recent studies showed that delayed recognition of symptoms in primary care leads to delayed referral and diagnostic delays.^{49,50} Patients with idiopathic pulmonary fibrosis have a poor quality of life already at diagnosis; therefore, early diagnosis and disease-specific treatment and supportive care strategies are crucial to preserve it.^{9,10} Cough, dyspnea, and fatigue are frequently underrecognized in primary care, leading to delays in referral.^{51,52} The use of generic PROMs and PREMs in primary care may bring

dyspnea and cough to light, raising the suspicion and early detection of the disease.

When patients are informed of this diagnosis, communication is frequently insensitive and incomplete, lacking empathy or expression of support; this has detrimental effects on how patients perceive their disease.^{53,54} The use of relational PREMs can explore patient experience, measuring if they were treated with empathy and the quality of communication and care provided.

The majority of patients do not receive holistic care, and their symptoms, psychosocial-emotional and caregiver needs are frequently overlooked.^{12,53,54} The CaNoPy study⁵⁵ revealed that the standard clinical assessments do not truly reflect patient experience of the disease. Bajwah et al²⁷ found that although all patients and their caregivers identified dyspnea as their main concern, their care providers had limited appreciation of its impact on patient's quality of life, showing that attention must be paid to detecting such needs and align provided care to the patient with idiopathic pulmonary fibrosis with individualized goals from the time of the diagnosis. In this context, PROMs and PREMs offer the possibility to make clinicians aware of what patients really feel, need, and want from the beginning of their journey.

On the other hand, the patients frequently experience fear, anxiety, worry, hopelessness, and helplessness and would like to discuss strategies to address their daily needs.^{12,53,54} To fill this gap, the multidisciplinary teams, including specialized nurse, physiotherapist, respiratory therapist, and social worker need training in best supportive and palliative care including meticulous needs assessment, symptom-relief strategies, and patient education. Patients' group educational meetings should be used to integrate the patient-centered approach. The use of PROs, PROMs, and PREMs in these situations can help identify common priorities and establish a shared understanding of anticipated outcomes and care experiences, thereby improving communication.

Tools such as the palliative care needs assessment tool in interstitial lung disease (NAT: PD-ILD),⁵⁶ symptom-assessment scales, and quality-of-life measures can provide useful measures to assess patients health and their lives at the time of the first assessment (Table 1). Other needs may not be captured by these tools; in that case, the measure yourself medical outcome profile (MYMOP) questionnaire⁵⁷ can be used. The advantage with MYMOP is that it asks the patient to identify the most important symptom instead of forcing fixed choices. In idiopathic pulmonary fibrosis, where education and information needs are largely unmet, use of MYMOP may allow patients to underscore this needs.

PROMs alone will not lead to improved outcomes without a change in clinicians' approach to care. Ramadurai et al⁵⁸ explored the education and information gaps and described both disease-specific as well as individualized content for both patients and caregivers: Education is key because it increases understanding, sense of control, and empowerment. Such information needs to be delivered at the first visit and revisited throughout the course of the disease.

Table 1 Patient Reported Outcome Measures (PROMs) and Patient Reported Experience Measures (PREMs) in Diagnosis and Treatment

Patient perspective (PRO)	Pitfalls	How to improve patient pathway	Potential PROMs and PREMs
Frequent delays in primary care ⁵⁴	Lack of: 1) attention to patient illness narratives; 2) IPF awareness	Improve access to secondary and tertiary care. Include patient perspective and increase IPF awareness	Assessment of well-being, health status (SF-36), ³³ and symptoms (MYMOP) ⁵⁷
Health care experience disconnected from patient reality and daily needs ^{54,79}	Lack of: 1) MDT and PC approach; 2) prioritization of symptom/need assessment; 3) integrated advanced care planning; 4) communication and information skills	Integrate PC approach within MDT, importance of symptom management, initiate early SCP discussions. Importance of discussion strategies about how to improve QoL, self-management, and empowerment	Symptom scale to detect needs (NAT, PD-interstitial lung disease, ⁵⁶ mMRC, ⁴² UCSD SOB, ⁴¹ LCQ, CQLQ) QoL measures: SGRQ-IPF, ³⁶ K-BILD, ³⁸ ATAQ-IPFca, ³⁷ L-IPF ³⁹ Relational PREMs to identify communications gaps, perceptions of poor care. PEI ⁸⁰ : to determine if patient received sufficient education
Adverse effects from antifibrotic therapies and resulting poor perceived QoL ^{12,81}	Lack of: 1) empathy and training in communication; 2) attention to patient narratives; 3) more therapeutic options; 4) integrated advanced care planning conversations; 5) MDT support and education	Perform routine needs assessment with good communication skills. Provide patient education and support. Facilitate inclusion of patient narratives. Integrate advanced care planning in specialist care. Provide well-trained care teams.	IPF-PREM: to explore patient and caregiver perceptions of care. HADS ⁴⁵ : to detect depression, anxiety, hopelessness. PESaM questionnaire (awaiting full validation) ⁴⁶
Need for support groups ⁵³	Lack of: 1) availability of support groups; 2) information about available support groups	Promote access to patient support groups. Provide information about available support groups	PEI, patient activation measure ^{11,46} : to measure enablement and patient activation of coping

ATAQ-IPF: the cross Atlantic tool to assess quality of life in IPF; CQLQ = cough quality of life questionnaire; HADS = Hospital Anxiety and Depression Scale; IPF = idiopathic pulmonary fibrosis; LCQ = Leicester Cough Questionnaire; L-IPF: Living with IPF, Tool to assess Quality of Life in IPF; MDT = multidisciplinary team; mMRC = modified Medical Research Council Dyspnoea Questionnaire; MYMOP = measure yourself medical outcome profile; NAT:PD = interstitial lung disease : palliative care needs assessment tool in interstitial lung disease; patient activation measure: Patient satisfaction, empowerment and activation; PC = palliative care; PEI = patient enablement instrument; PESaM = patient experiences and satisfaction with medications questionnaire; PRO = patient reported outcome; PROMs = patient reported outcome measures; PREM = patient reported experiences measures; QoL = quality of life; SF-36 = short form health survey 36; SGRQ-IPF: Saint George Respiratory Questionnaire – IPF; UCSD SOB = University of California San Diego Shortness of Breath Questionnaire.

Table 2 Patient Reported Outcome Measures (PROMs) and Patient Reported Experience Measures (PREMs) in Disease Progression and End of Life

Patient perspective (PRO)	Pitfalls	How to improve patient pathway	Potential PROMs and PREMs
Suboptimal or missing symptom management and resulting depression ²⁷	Lack of: 1) recognition of patient experience of disease; 2) training and education in PC; 3) evidence-based guidelines on PC treatment; 4) patient and caregiver reluctance to accept PC	Change philosophy and care delivery models with systematic symptom assessments and early integration of PC. Provide training in PC. Correct misperceptions of PC	NAT: PD-interstitial lung disease, ⁵⁶ MYMOP, ⁵⁷ MSAS, ⁸² UCSD SOB, ⁴¹ and cough specific tools: LCQ ⁴³ , CQLQ ⁸³ can detect burden and track changes with therapies
Poor perceived and worsened QoL (physical, psychosocial, emotional, spiritual, and existential needs) ^{27,58}	Lack of: 1) whole person approach; 2) standardized approach to needs assessment; 3) time to properly assess these needs	Provide strategies to preserve QoL Provide anticipatory guidance, use of symptom action plans. Educational resources for patients and caregiver	K-BILD, ³⁸ ATAQ-IPFca, ³⁷ SGRQ-IPF, ³⁶ L-IPF, ³⁹ NAT: PD-interstitial lung disease ⁵⁶ to assess and monitor QoL. Use of physical activity tracking
Significant burden from use of cumbersome oxygen delivery equipment ¹²	Lack of: 1) portable equipment for high-flow oxygen delivery; 2) education and support	Optimize oxygen delivery. Include dedicated staff in MDT for patient education and support	MYMOP ⁵⁷ to identify gaps and goals; IPF PREMs for communication and education gaps
Lack of psychological support ¹²	Lack of: 1) patient-centered care; 2) dedicated professionals in the MDT	Adopt patient-centered care with adequate MDT staffing	NAT: PD-interstitial lung disease ⁵⁶ (to detect unmet needs) HADS ⁴⁵ and MYMOP ⁵⁷ (depression)
Poor EoL care. Poor quality of dying and death ^{27,75,76}	Lack of: 1) PC approach and delayed referral; 2) clinical guidelines; 3) training in sensitive, patient-centered communication	Implement end-to-end patient-centered care models Adopt early advanced care planning Provide education and support to the MDT	NAT: PD-interstitial lung disease ⁵⁶ (for palliative care needs), MSAS, ⁸² MYMOP, ⁵⁷ L-IPF, ³⁹ K-B interstitial lung disease (to assess QoL and quality of dying), ³⁸ IPF-PREM (to assess care delivery processes)
Caregiver distress and increased burden ²⁷	Lack of: 1) understanding of the caregiver needs and engagement; 2) anticipatory guidance; 3) action plans and support for caregivers	Recognize caregiver in care Assess needs and provide relevant support Engage advanced care planning early Provide anticipatory guidance and services at home	Caregiver burden survey, to detect needs. ^{49,69} Need to develop tools to track panic episodes at home

ATAQ-IPF: the cross Atlantic tool to assess quality of life in IPF; CQLQ: cough quality of life questionnaire; HADS: hospital anxiety and depression scale; IPF: idiopathic pulmonary fibrosis; K-BILD: King's College Brief Interstitial Lung Disease Questionnaire; LCQ: Leicester Cough Questionnaire; L-IPF: Living with IPF- QoL tool; MD: multidisciplinary; MSAS = memorial symptoms assessment scale; MYMOP: measure yourself medical outcome profile; NAT:PD-interstitial lung disease : palliative care needs assessment tool in interstitial lung disease; PC: palliative care; PREM = patient reported experiences measures; PRO = patient reported outcome; PROMs = patient reported outcome measures; QoL: quality of life; SGRQ-IPF: Saint George Respiratory Questionnaire-IPF.

Advanced care planning is another important part of the patient-centered approach and needs to be addressed early at the beginning of the patient journey with idiopathic pulmonary fibrosis. It implies an interactive patient-centered communication process among patients, their families, and the health care providers.^{14,53,59} All major guidelines⁴⁸ endorse early advanced care planning discussions to: 1) alleviate patient and caregiver burden; 2) provide relevant information; 3) help prepare families for end of life; and 4) eventually deliver care in alignment with patient preferences. Unfortunately, more than 80% of the patients with pulmonary fibrosis do not have advanced care planning discussions and end up dying in hospital without any palliative care involvement.⁶⁰ At the core of these issues is an underlying misperception that palliative care is relevant only in end-of-life care. Therefore, most patients are referred too late and consequently also believe that palliative care is an end-of-life care only¹⁰.

Given the existing shortages of palliative-care experts, advanced care planning should be regarded as the responsibility of the specialist and primary care teams.⁶¹ Preliminary evidence suggests that implementing these conversations in tertiary clinics has direct impact on care.¹⁴ Further efforts are needed to develop advanced care planning models and PROs to assess its quality in idiopathic pulmonary fibrosis care.¹⁰

Pulmonary rehabilitation is an excellent opportunity to improve functional capacity and quality of life. Patients should be referred to such programs early and whenever possible as needs escalate. These programs can be tailored to meet the education and information needs, including advance care planning needs, in this patient population.

Caregivers should be involved and integrated early on in the patient journey. The devastating effects of idiopathic pulmonary fibrosis extend beyond patients, to their families and friends. Use of caregiver burden surveys may highlight their needs and lead to provide support or more resources to improve their living. Caregiver presence and ability to help is vital to patient well-being in this condition; therefore, care providers must actively seek out ways to identify and address caregiver concerns and to educate them on how to face the challenges of the disease.

PROGRESSION OF THE DISEASE

Idiopathic pulmonary fibrosis remains an unpredictable disease with varying rates of progression and inability to predict decline at individual level;^{7,48} acute exacerbations also recur.^{62,63} Most patients are not well informed about this, and uncertainty creates anxiety that affects their living. There is a need to educate patients on what to expect and how to prepare for future decline in an easy-to-understand fashion. This type of education must be individualized because the rates of progression will vary among individuals.⁶⁴

Impairment of quality of life in idiopathic pulmonary fibrosis is largely driven by worsening of symptoms, such as dyspnea, cough, and fatigue over time.^{10,27,65} Daily activities, recreation, pleasure, and employment are often directly affected by the burden of symptoms; anxiety, depression, and

social isolation result from the limitations caused by the disease (Table 2). Currently, there are no dyspnea questionnaires that capture the newly defined episodic breathlessness that may require different treatment strategies.^{66,67} Many patients report that the practical information needed to live with their disease is generally missing,⁶⁸ perceiving that care in the specialist centers tends to be “disease-centric” without enough emphasis on symptom management, living life well, maintaining hope, and preparing for death with dignity.⁶⁹ Mularksi et al recommend that patients and caregivers should be provided dedicated dyspnea education and action plans as part of home dyspnea management.⁷⁰ Dyspnea self-management in idiopathic pulmonary fibrosis is not described outside of a few case reports.^{59,71} As disease and symptom needs progress, the efforts to address education and information need to follow in parallel. The use of PREMs and PROMs (Table 2) in this context can lead to recognition of patient needs and prompt required action by the multidisciplinary team.

In addition, the patients want to be supported outside the clinic: The CaNoPy study⁶⁹ highlighted the patients’ need to identify early deterioration and to start simple interventions—such as timely supplemental oxygen—to preserve quality of life without waiting for follow-up clinic appointments. These findings suggest that self-monitoring and management at home are important patient’s needs to regain a sense of control and to feel empowered. In this context, PROMs can be easily monitored, detect clinical changes, and lead to meaningful early interventions. Scales to measure self-efficacy, confidence, and patient activation measure¹¹ along with symptom scales and needs-assessment tools can also be useful to assess impact of interventions.

Furthermore, most patients in this phase want information about decline and end of life. Advanced care planning discussions can address these needs by identifying wishes, providing context discussing clinical and functional status, and engaging patients in shared decision making.⁵⁹ It is paramount to ask patients directly; therefore, PROMs are invaluable in this situation.

Education of caregivers on how to recognize and handle worsening is essential in idiopathic pulmonary fibrosis care. Caregivers are often not prepared to help their loved ones, and both describe being overcome with frustration, hopelessness, and helplessness.⁷² Continued caregiver engagement in care process and decision making is, therefore, desirable in idiopathic pulmonary fibrosis.⁵⁹ Preliminary data show that collaboration between support groups and community services improves care and reduces hospitalizations at end of life.^{73,14} Additionally, patients with pulmonary fibrosis find support groups to be instrumental in developing positive thinking, learning how to cope well, and using emotion-focused strategies to overcome depression and to reduce social isolation.⁷⁴

END OF LIFE

End-of-life care in idiopathic pulmonary fibrosis is poor and it is marked by lack of timely and appropriate palliative care

access, symptom management, and advanced care planning.^{75,76} Several studies pointed to a very high caregiver burden because of the lack of a patient- and family-centered approach to care and easy access to community resources for support.^{54,69,72} Ahmadi et al⁷⁵ and Rajala et al⁷⁶ have shown that most patients die in hospitals with aggressive, costly, and ineffective therapies; poor symptom assessment and control; and low family presence at death. Death is “unexpected,” and there is no anticipatory guidance for families and inadequate bereavement support. When compared to lung cancer, end-of-life care in idiopathic pulmonary fibrosis is poorer.⁷⁵ Qualitative data from patient, caregiver, and care provider interviews indicate the lack of expertise in dealing with idiopathic pulmonary fibrosis-specific end-of-life issues and the urgent need to develop symptom management protocols.^{59,77} An explorative analysis suggested that early implementation of palliative care can result in greater concordance between patient preferences and care provided, increase home deaths, and reduce end-of-life acute care use.^{14,76} Bereaved caregivers who experienced early integrated palliative approach in idiopathic pulmonary fibrosis care in collaboration with the multidisciplinary team reported being better prepared for end of life, improved quality of life, and better quality of dying.^{14,77}

In conclusion, palliative care processes must begin early with meaningful advanced care planning conversations, systematic and ongoing needs assessment, integrated symptom management, anticipatory guidance, education, and support that can effectively address issues and questions when the disease worsens. The use of PROMs and PREMs can play a major role in this process (Table 2), helping in identifying patient and caregivers needs.

CONCLUSIONS

Advocacy bodies, policy makers, regulatory authorities, pharmaceutical industry, and health care systems, including patients and their caregivers, recognize the need for the use of PROs, PROMs, and PREMs in idiopathic pulmonary fibrosis. Their use can improve care and research, facilitate patient-centered care by identifying needs, and informing care decisions. It must be recognized that patient needs and experiences are as important as objective measures in the health outcomes assessment and shared care decisions with the patients. Knowledge translation cannot occur without changing attitudes, culture of practice, and removing practical barriers to provision of patient-centered care.

An ideal setting to implement PRO, PROM, and PREM is the idiopathic pulmonary fibrosis multidisciplinary team. Many questions regarding its composition and governance remain unanswered, requiring further studies to better define the role of these tool in earlier diagnosis, better management, and follow-up. The ability to assess and control symptoms; develop self-efficacy; access to psychosocial, emotional, and spiritual support; and information on the disease and its course are important unmet needs for both patients with idiopathic pulmonary fibrosis and caregivers.^{11,12,49,69} Furthermore, PROs, PROMs, and PREMs need to be validated to

accurately identify patient needs, to measure efficacy of interventions, to improve various domains of quality of life and care, and to address educational needs at various time points in the disease course.

There is a huge need to support the multidisciplinary work focused on identifying gaps across the patient journey, and PREMs and PROMs can be instrumental to this goal.^{9,10} Digital patient interfaces are already available, allowing their measurement at chosen time points,⁷⁸ with scores made readily available for decision making at the time of patient clinical encounters.
